Rational construction of layered MoS<sub>2</sub> nanostructures (nanotubes, nanosheets, nano-flowers) for morphological control and composite of other carbon-based materials is an effective way to develop high-performance energy storage electrode materials. Is Mos 2 a suitable material for energy-based applications? 5. Conclusion and future perspective MoS<sub>2</sub> has been emerged as the most attractive material among various TMDs for various energy-based applications including LIBs, SCs, and HERs on account of its layered structure, large surface area, multi-valent Mo-atom, and active edge sites. What is the specific discharge capacity of Mos 2 /graphene composite materials? Specifically, after 250 cycles at a current density of 300 mA/g, the specific discharge capacity remained at 421 mA h/g. Moreover, this method offers high yield and low cost, making it highly attractive for large-scale production of MoS<sub>2</sub> /graphene composite materials for energy storage applications. Does Mos 2 3D heterostructure improve electrochemical performance? It exhibited remarkable rate performance and coulombic efficiency, with a maximum specific capacity of 1 454 mA h/g. The experiment proved that MoS<sub>2</sub> 3D heterostructure can expose more active sites and doping with other materials, which is conducive to enhancing electrochemical performance. How is Mos 2 dispersed in centrifugation? After centrifugation, the supernatant was used to extract a few or a single layer of MoS<sub>2</sub> using N-Methylpyrrolidone (NMP) as a dispersant. The film is created by applying the stripped material, dispersion solution, etc., onto the surface of the target substrate. Fig. 6.
