In a recent issue of *Angewandte Chemie*, Chen et al. proposed a new concept of spatiotemporal phase change materials with high supercooling to realize long-duration storage and intelligent release of latent heat, inspiring the design of advanced solar thermal fuels. Phase change materials (PCMs) represent a pivotal class of substances that store and release thermal energy through reversible transitions between solid and liquid states. Their ability to absorb or release large quantities of latent heat at nearly constant temperatures makes them ideal for thermal energy storage. Phase change materials (PCMs), capable of reversibly storing and releasing tremendous thermal energy during nearly isothermal and isometric phase state transition, have received extensive attention in the fields of energy decarbonization, passive thermal management, etc. Developing pure or composite latent heat storage materials is associated with phase transitions and the materials that are used to store energy related to latent heat are referred to as phase change materials. Two common phase transitions that are used for latent heat energy storage are the solid to liquid transition, such as the melting of ice.
