Phase change materials (PCMs) represent a pivotal class of substances that store and release thermal energy through reversible transitions between solid and liquid states. Their ability to absorb or release large quantities of latent heat at nearly constant temperatures makes them ideal for thermal energy storage. Physical phase change energy storage represents a transformative method of energy management by utilizing materials that undergo phase transitions to store and release energy efficiently. This approach capitalizes on the energy absorbed or released during phase changes, such as melting or solidification. Phase Change Thermal Energy Storage (PCTES) is a type of thermal energy storage that utilizes the heat absorbed or released during a material's phase change (e.g., from solid to liquid or vice versa) to store and recover thermal energy. This technology is key in enhancing energy efficiency in buildings and industrial processes.
